**Resonant detection or identification antenna
insensitive to its environment**

5 The present invention relates to a resonant detection
or identification antenna of the type comprising at
least one turn which comprises at least one
electrically conducting wire and is connected to a
transponder electronic chip, the operating frequency of
the said antenna being greater than or equal to 10 MHz,
10 the area defined by the said at least one turn being
substantially less than or equal to 0.30 m^2 .

The antenna forms a resonant circuit operating at high
frequency, the value of which is predetermined so as to
15 pick up sufficient energy to supply the electronic
chip. The chip is thus said to be a passive chip.

Such antennas are, for example, used in the field of
contactless identification and in the field of
20 detection in antitheft systems. These antennas are also
commonly called "labels", their area not exceeding
 0.30 m^2 and their operating frequencies being high
(above 10 MHz).

25 The resonant antennas are constructed in such a way
that their inductance matches the capacitance of the
circuit. This capacitance is in practice close to that
of the electronic chip. Now, such circuits are very
sensitive to the environment as this behaves as a
30 dielectric medium that particularly affects the
capacitance of the circuit.

It is consequently very difficult to produce antennas
whose operation is not impaired by a change in medium.
35 In particular, when the resonant antenna is integrated
into a player's identification number, and is therefore
in contact with a human being, the capacitance of the
circuit increases. To solve this drawback, it has been
envisaged to modify the shape of the antenna or else to

modify the number of turns of the antenna. However, the envisaged solutions do not provide satisfactory results.

5 The object of the present invention is in particular to remedy the aforementioned drawbacks by providing a resonant antenna that is virtually insensitive to the environment in which it is placed, and to do so by simple, effective and inexpensive means.

10

For this purpose, according to the invention, a resonant antenna of the kind in question is essentially characterized in that the total capacitance of the antenna is substantially greater than or equal to
15 140 pF and in that the Q-factor of the said at least one turn is substantially greater than or equal to 30.

Thanks to these arrangements, an antenna whose operating characteristics are not modified by the
20 environment has been surprisingly obtained.

Advantageously, the transponder chip has a first capacitor of predetermined value and in that a second capacitor is placed in parallel with the electronic
25 chip in such a way that the overall capacitance of the antenna is greater than or equal to 140 pF. It is thus easy to match the capacitance of the antenna according to the capacitance of the chip, which is predetermined during fabrication.

30

Preferably, the said at least one turn has mechanical properties suitable for the antenna to retain by itself a predetermined shape. The antenna can therefore be used in the form of a bracelet or collar.

35

In one advantageous embodiment, the said at least one turn is fastened to a support.

Also preferably, the said at least one turn comprises a single-strand wire.

Advantageously, the said at least one turn comprises a
5 wire formed from seven strands and the diameter of which is substantially equal to 0.25 mm, for example.

Preferably, the said at least one turn takes the form of a track deposited on a substrate and the width and
10 the thickness of which are substantially equal to at least 1.4 mm and 35 μ m respectively.

Also advantageously, the antenna comprises a single
15 turn.

Preferably, the single turn is chosen from one of the rectangular shapes having recessed corners and rectangular shapes having cut corners.

20 As a variant, the antenna comprises a first turn and a second turn which is placed inside the first turn and the area of which lies substantially between 10% and 90% of the area of the said first turn.

25 Preferably, the area of the second turn is substantially equal to half the area of the first turn.

Other features and advantages of the invention will appear over the course of the following description of
30 two of its embodiments given by way of non-limiting example and in conjunction with the appended drawing.

Figure 1 shows a resonant antenna according to a first embodiment of the invention, associated with a player's
35 identification number.

Figure 2 is a plan view of a resonant antenna according to a second embodiment of the present invention.

Figures 3 and 4 are plan views of an antenna according to third and fourth embodiments of the present invention.

- 5 Figure 1 shows a preferred but non-exclusive form of a resonant antenna 1 or label according to the invention, associated with a player's identification number 2. The antenna 1 has a small thickness.
- 10 The antenna 1 thus comprises, for example, three turns 3, 4 and 5 of rectangular shape. Of course, the shape of the turns may differ, it being possible for the turns to be of square, circular, elliptical or even hexagonal shape. The shape of the turns is chosen
- 15 according to the application of the antenna.

The resonant antenna 1 constitutes a supply and transmission antenna for a transponder chip 7 which is itself attached to the support or player's number 2.

20

The electronic chip 7 used is known per se and operates at high frequency, the value of which is greater than or equal to 10 MHz, for example at a frequency of 13.56 MHz. This chip possesses intrinsic

25 characteristics such as its capacitance. The value of this capacitance is determined during fabrication of the chip.

Of course, the antenna according to the invention may

30 be used at other frequencies.

Within the context of the invention, the antenna 1 is said to be of small thickness insofar as the area of the constituent turns is substantially greater than the

35 thickness of this antenna. The area bounded by the turns is small, i.e. less than or equal to 0.30 m^2 . For example, it may be a square with sides of 0.5 m.

In addition, it will be readily understood that this antenna may consist of a single turn 3 connected to the chip 7.

5 According to another essential feature of the invention, the antenna 1 is constructed so that its overall capacitance is greater than or equal to 140 pF and so that the Q-factor of the coil formed by the turns 3 to 5 (or the turn 3 in the case of a single
10 turn) is greater than or equal to 30.

Insofar as the capacitance of the electronic chip cannot, by construction, reach this 140 pF threshold value, the present invention advantageously provides
15 for a second capacitor 8 to be placed in parallel with the chip 7. The value of this second capacitor is matched to that of the electronic chip 7 so that the total capacitance of the antenna is greater than or equal to 140 pF.

20 The value of the total capacitance may also be achieved in several other different ways such as, for example, by having several localized capacitors placed at several points in the loop or else localized capacitors
25 associated with distributed capacitors obtained from plates, screens or cable jackets.

The turns 3 to 5 are made, for example, of a copper or aluminium alloy and their geometrical characteristics
30 are designed so as to obtain a Q-factor of greater than or equal to 30.

Thus, a resonant antenna 1 insensitive to its immediate environment is obtained.

35 Each turn may be a single-strand or multistrand turn. The antenna may thus comprise a wire formed from seven strands, the overall diameter of the wire being about 0.25 mm. The antenna may have a rectangular shape, the

length of which is around 190 mm and the width is about 160 mm.

5 The support 2 to which the antenna is fastened may be made of a material of any type, such as plastic, glass, cardboard, leather, wood, nonwoven fabric or woven fabric.

10 The turns 3 to 5 may be fastened to the support 2 employing any known technology. The turns may take the form of tracks deposited, for example, by etching or printing, or any other process for depositing a conductive material.

15 By way of non-limiting example, the track obtained has a width of 1.4 mm and a thickness of 35 μm .

20 Moreover, it is possible for the label 1 not to be fastened to a support. The turns, or the single turn, are in this case obtained from a material whose mechanical properties allow the turn (or turns) to be supported by itself (or themselves). The antenna may for example take the form of a single turn made from a wire comprising 7 to 19 strands, the diameter of the
25 wire then being close to 0.5 mm.

Moreover, in a second embodiment, as shown in Figure 2, the antenna 10 may have any shape matched to the support to which it is intended to be fixed, such as
30 for example a case of approximately rectangular shape.

To achieve the same capacitance, area and Q-factor characteristics as in the first embodiment, while still taking into account the environment in which it is placed, this antenna may, for example, consist of a
35 first turn 11 and a second turn 12, one of which is placed inside the other and has a smaller area.

For example, the second turn 12 is placed inside the first turn 11 and this second turn 12 has an area of between 10% and 90% of the area of the first turn 11. In the present case, the second turn 12 is
5 approximately equal to half the area of the first turn 11.

Thus, the first turn 11 extends along the second turn 12 only over a fraction of its length.
10

Of course, these turns are also connected to the electronic chip 7 described above.

Moreover, as described with regard to the first
15 embodiment, the antenna may comprise a single turn (connected to a chip and optionally to one or more additional capacitors). This turn may be variously shaped, while maintaining the same perimeter, in order for the resonant frequency of the antenna to be
20 perfectly tuned to the desired frequency. For example, as shown in Figure 3, the antenna 20 comprises a single cross-shaped turn 21 (a rectangular shape whose corners have been recessed). As a variant, the antenna 30 shown in Figure 4 again comprises a single turn 31 of
25 rectangular shape, the corners of which have been cut off.

Of course, the resonant antenna according to the invention is not limited to the preferred embodiments
30 described above by way of example, but on the contrary it embraces all alternative embodiments falling within the scope of the claims appended hereafter.
